# CS 221 Lecture 9 

## Tuesday, 1 November 2011

Some slides in this lecture are from the publisher's slides for Engineering Computation: An Introduction

Using MATLAB and Excel
© 2009 McGraw-Hill

## Today's Agenda

1. Announcements
2. Passing functions as parameters to other functions
3. Solving equations
4. Numerical Root-finding methods (Text: Ch. 6)
a. Bisection
b. Newton's Method
c. MATLAB's built-in methods: fzero() and roots()
5. Lab Quiz - What to expect

## 1. Announcements

- Problem Set 3 is out
- Due Monday 7 November
- Lab Quiz 2 this Thursday
- All-MATLAB
- Example problems later \& posted on Web page

## 2. Functions As Parameters

- Sometimes it's useful to pass a function as a parameter to another function
- You want to use a function without knowing exactly what it is
- This is useful for:
- Plotting - see fplot()
- Numerical (not symbolic) manipulations
- Integration: finding the area under the curve of $f(x)$
- Finding roots of equations $f(x)=0$

## Two Ways to Pass Functions As Parameters

1. Pass the name of the function as a string (in quotes)
Examples:
fplot('cos', [-pi, pi])
g('f',1,2)
2. Pass the name of the function preceded by @

- Syntax: @funcname
- Semantics: @cos is a function handle - a pointer to the cosine function
Examples
fplot(@cos, [-pi, pi])
g(@f,1,2)

## Function Handles have many uses.

- You can assign a function handle to a variable func = @cos;
Now func( x ) returns the same thing as $\cos (\mathrm{x})$
- Pass a parameter to a user-defined function

Example: bisect() - coming soon

- Use of function handles is required
- "function handle" is a real type in MATLAB
- like "double" or "char"

## 3. Solving Equations

- We consider algebraic equations of the form:

$$
f(x)=0
$$

Single unknown: x

- Linear: multiply and add constants:

$$
f(x)=3 x+4.0321 ;
$$

- Polynomials:

Sums of (non-negative) integer powers of $x$, multiplied by real constants

$$
f(x)=3 x^{5}+2.5 x^{3}+x^{2}+100 x-10.5
$$

- General Nonlinear

Non-integer powers of $x$, transcendentals, logs, etc:
$f(x)=x^{3 / 2}+\log x+x \sin x$

## Finding Roots of Equations

- We want the equation in the form $\mathrm{f}(\mathrm{x})=0$
- This may may require some massaging
- Example:

$$
7 y=6
$$

- If we say that

$$
f(y)=7 y-6
$$

then when $f(y)=0$, the equation is satisfied

## Solution Approaches

- Analytical (algebra)
- What you've been doing since high school
- Fine for linear and some polynomial equations
- Often impractical in "real world" situations
- Graphical
- Plot the function see where it crosses the $x$-axis
- Numerical

# 4. Numerical Root-Finding Methods 

## Finding Roots

- Problem: given $f(x)$, find the roots of $f$
- I.e., value(s) of $x$ for which $f(x)=0$
- Approaches:
- Solve analytically
- Quadratic equations, some polynomials, ...
- Solve graphically
- Low precision
- Solve numerically
- When the other methods aren't adequate
- All you need is the function itself

That is: you give it $x$, it gives back $f(x)$

## Graphical Method

- Graph the function in the region of interest
- See where it crosses the $y$-axis

## Finding Roots Numerically: General Approach

<Given function f plus starting_info>
<initialize>
estimate = <set based on starting_info>
while estimated_error > error_spec
old_estimate = estimate;
estimate = <refine estimate, using f>;
estimated_error $=\quad \%$ update the error estimate
(old_estimate - estimate)/estimate;
end

## The Bisection Method

- Principle:

If the signs of $f(m)$ and $f(n)$ differ, there exists an odd number of roots (at least 1 ) between $m$ and $n$ ...or there is a discontinuity between m and n

- Method:
- Find $m$ and $n$ such that $f(m) \times f(n)<0$
- Compute $r=(m+n) / 2$ and $f(r)$
- If $f(r)$ has the same sign as $f(m)$, replace $m$ by $r$ else [f(r) has same sign as $f(n)$ ] replace $n$ by $r$

## Bisection Method: Error estimation

- We know there is a root between $m$ and $n$
- Estimate $=(f(m)+f(n)) / 2$
- Root must be within $(f(m)-f(n)) / 2$ of this estimate!
- The interval [m,n] shrinks with every iteration!

## Bisection Method: Error estimation

- We know there is a root between $m$ and $n$
- Estimate $=(f(m)+f(n)) / 2$
- Root must be within $|\mathrm{m}-\mathrm{n}| / 2$ of this estimate!
- The interval [m,n] shrinks with every iteration

## Bisection Method: Error estimation

- We know there is a root between $m$ and $n$
- Estimate $=(f(m)+f(n)) / 2$
- Root must be within $|\mathrm{m}-\mathrm{n}| / 2$ of this estimate!
- The interval [m,n] shrinks with every iteration

## Bisection Method Example

- Consider the function $\mathrm{f}(\mathrm{x})=7 \mathrm{y}-6$
- Consider an initial interval of $x_{\text {low }}=-10$ to $x_{\text {hi }}=10$

$$
\begin{aligned}
f(-10) & =-76 \\
f(10) & =64
\end{aligned}
$$

- Since the signs are opposite, we know that the method will converge to a root of the equation
- The value of the function at the midpoint of the interval is:

$$
f(0)=-6
$$

## Bisection Method Example

- The method can be better understood by looking at a graph of the function:

Engineering Computation: An Introduction
Using MATLAB and Excel

## Bisection Method Example

- Now we eliminate half of the interval, keeping the half where the sign of $f$ (midpoint) is opposite the sign of $f$ (endpoint)
- In this case, since $f\left(x_{\text {mid }}\right)=-6$ and $f\left(x_{\text {upper }}\right)=64$, we keep the upper half of the interval, since the function crosses zero in this interval

## Bisection Method Example

- The interval has now been bisected, or halved:

Engineering Computation: An Introduction
Using MATLAB and Excel

## Bisection Method Example

- New interval: $x_{\text {lower }}=0, x_{\text {upper }}=10, x_{\text {mid }}=5$
- Function values:

$$
\begin{gathered}
f(0)=-6 \\
f(5)=29 \\
f(10)=64
\end{gathered}
$$

- Since $f\left(x_{\text {lower }}\right)$ and $f\left(x_{\text {mid }}\right)$ have opposite signs, the lower half of the interval is kept

## Bisection Method Example

- At each step, the difference between the high and low values of $x$ is compared to $2^{*}$ (allowable error)
- If the difference is greater, than the procedure continues
- Suppose we set the allowable error at 0.0005 . As long as the width of the interval is greater than 0.001 , we will continue to halve the interval
- When the width is less than 0.001 , then the midpoint of the range becomes our answer

## Bisection Method Example

- Or course, we know that the exact answer is $6 / 7$ (0.857143)
- If we wanted our answer accurate to 5 decimal places, we could set the allowable error to 0.000005
- This increases the number of iterations only from 16 to 22 - the halving process quickly reduces the interval to very small values
- Even if the initial guesses are set to -10,000 and 10000, only 32 iterations are required to get a solution accurate to 5 decimal places

## Bisection Method Example - Polynomial

- Now consider this example:

$$
x^{2}-2 x=8
$$

- Use the bisection method, with allowed error of 0.0001

## Bisection Method Example - Polynomial

- If limits of -10 to 0 are selected, the solution converges to $x=-2$

## Bisection Method Example - Polynomial

- If limits of -10 to 10 are selected, which root is found?
- In this case $f(-10)$ and $f(10)$ are both positive, and $f(0)$ is negative

## Bisection Method Example - Polynomial

- Which half of the interval is kept?
- Depends on the algorithm used - in our example, if the function values for the lower limit and midpoint are of opposite signs, we keep the lower half of the interval

## Bisection Method Example - Polynomial

- Therefore, we converge to the negative root

Engineering Computation: An Introduction
Using MATLAB and Excel

## Bisection Method - Summary

- A "bracketing" method
- Guaranteed to converge
- May take a long time to converge if root is near one of the bounds
- Provides guaranteed upper bound on the absolute (not relative!) error

## "Open" Root-finding Methods

- Bisection method requires two input x-values for which the sign of $f(x)$ differs
- They thus bracket the root
- These are called "closed" methods
- "Open" methods do not require knowledge of where the root lies
- Some only need one initial guess
- BUT they may not converge

## Newton' s Method

- Newton' s Method (also know as the NewtonRaphson Method) is another widely-used algorithm for finding roots of equations
- In this method, the slope (derivative) of the function is calculated at the initial guess value and projected to the $x$-axis
- The corresponding $x$-value becomes the new guess value
- The steps are repeated until the answer is obtained to a specified tolerance

## Newton' s Method

Using MATLAB and Excel

## Newton' s Method

New guess for $x$ :
$x_{\mathrm{n}}=x_{\mathrm{i}}-y\left(x_{\mathrm{i}}\right) / y^{\prime}\left(x_{\mathrm{i}}\right)$

Using MATLAB and Excel

## Newton' s Method Example

- Find a root of this equation:

$$
y=3 x^{3}-15 x^{2}-20 x+50
$$

- The first derivative is:

$$
y^{\prime}=9 x^{2}-30 x-20
$$

- Initial guess value: $x=10$

## Newton's Method Example

- For $x=10$ :

$$
\begin{gathered}
y=3(10)^{3}-15(10)^{2}-20(10)+50=1350 \\
y^{\prime}=9(10)^{2}-30(10)-20=580 \\
x_{n}=10-1350 / 580=7.6724
\end{gathered}
$$

- This is the new value of $x$

## Newton’ s Method Example

Using MATLAB and Excel

## Newton' s Method Example

- For $x=7.6724$ :

$$
\begin{gathered}
y=3(7.6724)^{3}-15(7.6724)^{2}-20(7.6724)+50=368.494 \\
y^{\prime}=9(7.6724)^{2}-30(7.6724)-20=279.621 \\
x_{n}=7.6724-368.494 / 279.621=6.3546
\end{gathered}
$$

## Newton' s Method Example

Using MATLAB and Excel

## Newton' s Method Example

- Continue iterations:

| x-initial | $y(x)$ | $y^{\prime}(x)$ | $x$-new |
| :---: | :---: | :---: | :---: |
| 10.0000 | 1350.0000 | 580.0000 | 7.6724 |
| 7.6724 | 368.4941 | 279.6210 | 6.3546 |
| 6.3546 | 87.0049 | 152.7887 | 5.7851 |
| 5.7851 | 13.1273 | 107.6559 | 5.6632 |
| 5.6632 | 0.5457 | 98.7502 | 5.6577 |
| 5.6577 | 0.0011 | 98.3529 | 5.6577 |
| 5.6577 | 0.0000 | 98.3521 | 5.6577 |

## Newton's Method Example

- To find the other roots, use different initial guess values

| x-initial | $y(x)$ | $y^{\prime}(x)$ | $x$-new |
| :---: | :---: | :---: | :---: |
| 0.0000 | 50.0000 | -20.0000 | 2.5000 |
| 2.5000 | -46.8750 | -38.7500 | 1.2903 |
| 1.2903 | 5.6645 | -43.7253 | 1.4199 |
| 1.4199 | -0.0503 | -44.4518 | 1.4187 |
| 1.4187 | 0.0000 | -44.4468 | 1.4187 |
|  |  |  |  |
| x-initial | $y(x)$ | $y^{\prime}(x)$ | $x-n e w$ |
| -5.0000 | -600.0000 | 355.0000 | -3.3099 |

Engineering Computation: An Introduction
Using MATLAB and Excel

## Newton' s Method Example

- Three roots found:

Engineering Computation: An Introduction
Using MATLAB and Excel

## Newton' s Method - Comments

- Usually converges to a root much faster than the bisection method
- In some cases, the method will not converge (discontinuous derivative, initial slope $=0$, etc.)
- In most cases, however, if the initial guess is relatively close to the actual root, the method will converge
- Don' t necessarily need to calculate the derivative: can approximate the slope from two points close to the $x$-value. This is called the Secant Method

## Newton-Raphson Method

- Advantages:
- Fast convergence
- Error on $\mathrm{i}+1^{\text {st }}$ iteration proportional to square of error on $\mathrm{i}^{\text {th }}$ iteration
- Number of correct decimal places roughly doubles each iteration (assuming convergence!)
- Disadvantages:
- Derivative must be known
- No general convergence criterion
- Implementation suggestions:
- Include a limit on number of iterations
- Check for $\mathrm{f}^{\prime}(\mathrm{x})=0$ during computation

## MATLAB's Built-in Root-finding Tools

## fzero()

- root = fzero(@func,[low,high]);
- root = fzero(@func,guess);
- Uses a combination of methods
(See the help under "finding roots")
roots()
- Solves for all roots of a polynomial

## roots Example

- For polynomials, the MATLAB function roots finds all of the roots, including complex roots
- The argument of roots is an array containing the coefficients of the equation
- For example, for the equation

$$
y=3 x^{3}-15 x^{2}-20 x+50
$$

the coefficient array is $[3,-15,-20,50]<$

## roots Example

$$
\begin{aligned}
& \gg A=[3,-15,-20,50] ; \\
& \gg \operatorname{roots}(A) \\
& \text { ans }= \\
& \quad 5.6577 \\
& -2.0764 \\
& \quad 1.4187
\end{aligned}
$$

## roots Example

- Now find roots of

$$
y=3 x^{3}-5 x^{2}-20 x+50
$$

$$
\left.\begin{array}{l}
\text { >> } B=[3,-5,-20,50] ; \\
\gg \operatorname{roots}(B) \\
\text { ans }= \\
\quad-2.8120 \\
\quad 2.2393+0.9553 i \\
\quad 2.2393-0.9553 i
\end{array}\right\} \text { Two complex roots } \quad l
$$

## 5. Lab Quiz - What to Expect

- One problem will involve correcting a script
- it will likely involve fprintf(), logic, iteration
- One problem will involve writing a function from scratch
- it will involve computing with arrays
- it will involve iteration (while- and/or for-loops)

## Example

Here's a function that is supposed to return a vector whose elements are the differences between adjacent elements in the input vector. Correct it:
function $x=$ vecdiff(invec)
len = size(invec);
for $\mathrm{i}=1$ :len

$$
x(i)=\operatorname{invec}(i)-\operatorname{invec}(i+1) ;
$$

end
end

## Example, cont.

- For input: [ 0, 3, -20, 8, 10, 7 ]
- Correct return value is: [ $3,-23,28,2,-3$ ] function $x=$ vecdiff(invec)
len = size(invec);
for $\mathrm{i}=1$ :len
$x(i)=\operatorname{invec}(i)-\operatorname{invec}(i+1) ;$
end
end

## Example

- Write a function that takes a 2-dimensional matrix and returns the maximum difference between any two elements
